Example Wiring Diagram showing WattMaster Refrigeration System Module for Variable Speed Compressors, Copeland Inverter, Electronic Expansion Valve, and Variable Speed Condenser Fan Control
Introduction
This document provides instructions on how the variable speed scroll compressor and inverter drive are applied to a variable speed compressor in a safe and reliable manner. The variable speed scroll compressor will be referred to throughout this document as the “variable speed compressor” or the “compressor”. The inverter drive will be referred to throughout this document as the “inverter drive” or simply the “drive”.

Variable Speed Scroll Compressors
Product Description
The variable speed compressor has a speed range of 900 (refer to operating envelope for low speed operation) to 5000 revolutions per minute and is intended for use in commercial air conditioning, chiller, and heat pump applications. The variable speed scrolls utilize three-phase brushless permanent magnet (BPM) motors. The compressors have been qualified for use with drives which have been developed and qualified for BPM motor-compressors.

Compressor Motor
The brushless permanent magnet (BPM) motor in the variable speed scroll consists of a three-phase stator and a rotor embedded with high energy permanent magnets. The input voltage is a series of pulses of varying frequency at 120 degree intervals between phases.

Oil Pump
The variable speed scroll is equipped with an oil pump to ensure an adequate supply of oil to the bearing system throughout the operating speed range of 900 to 5000 RPM.

Compressor Temperature Protection
A discharge line thermistor must be used to protect the compressor. The drive will shut down the compressor when the thermistor temperature exceeds 275°F (135°C).

Oil Recovery
An oil recovery cycle is required if compressor speed is below 1,800 rpm for 2 hours. When this occurs, the unit controls will increase the compressor speed to 3,600 rpm for five minutes.

Motor Protection
The drive includes motor protection features for the compressor. The drive sets the maximum current limit, low voltage fold back which allows the compressor to ride through low voltage situations, which helps keep the compressor running to avoid nuisance trips.

Starting and Stopping Routine
The drive controls the starting and stopping routine of the variable speed scroll. This routine allows soft starting and controlled stopping, an advantage over traditional on-off control of fixed capacity units. Please refer to Table 4 for an exact explanation of the starting and stopping process.

The variable speed scroll compressor incorporates a fluid brake design to help mitigate reverse rotation during shutdown. A momentary reverse rotation sound may be heard.
**Oil Type**
Variable speed scrolls are charged with polyolester (POE) oil. See the compressor nameplate for the original oil charge. A complete recharge should be approximately four fluid ounces (118cc) less than the nameplate value. Copeland™ Ultra 32 3MAF, available from Emerson Wholesalers, should be used if additional oil is needed in the field. Mobil Arctic EAL22CC, Emkarate RL22, Emkarate 32CF and Emkarate 3MAF are acceptable alternatives.

![Caution]

POE oil must be handled carefully and the proper protective equipment (gloves, eye protection, etc.) must be used when handling POE lubricant. POE must not come into contact with any surface or material that might be harmed by POE, and spills should be cleaned up quickly with paper towels, soap and water.

**Maximum Tilt Angle**
Service personnel may be required to maneuver a unit through a stairwell or other cramped area that might require tilting the unit. The maximum allowable tilt angles from horizontal for individual compressors (not tandem or trio applications) are summarized below:

Max. tilt angle with compressor not running = 60°

**Contaminant Control**
Moisture levels should be maintained below 50 ppm for optimal performance. A filter-drier is required on all R-410A and POE lubricant systems to prevent solid particulate contamination, oil dielectric strength degradation, ice formation, oil hydrolysis, and metal corrosion. Molecular sieve and activated alumina are two filter-drier materials designed to remove moisture and mitigate acid formation. A 100% molecular sieve filter can be used for maximum moisture capacity. A more conservative mix, such as 75% molecular sieve and 25% activated alumina, should be used for service applications.

**Discharge Check Valve**
The compressor uses a shutdown valve located in the discharge fitting. This check valve is not a low-leak-back check valve and will leak when pressure differential across the check valve is low.
The BPM motors used in the variable speed scrolls are three-phase. The three windings should always have line to line continuity because there is no internal overload at the center of the motor windings to open and take the motor off-line. If one or more of the windings shows continuity to ground, the compressor must be replaced.

Measuring the current in the three individual wires feeding the compressor will provide no useful information to the service technician, other than to show that each winding of the compressor is drawing current. The more appropriate measurement is the current input to the drive. Current input to the drive can be compared to the published values of MCC and RLA.
Three Phase Series Variable Speed Drives

Product Description
The inverter drive has been developed specifically for the variable speed compressor. The drive will power the compressor, control the compressor running speed, provide compressor and drive protection and communicate with the master controller. The drive requires cooling and is typically installed in the unit near the compressor.

Theory of Drive Operation
The primary purpose of the drive is to convert the 60 Hz AC input voltage into a variable frequency, variable voltage output to power the variable speed scroll compressor. The drive conditions the AC input Voltage through a series of conditioning processes to arrive at the desired output. The drive first converts the AC input voltage into a DC bus. The DC voltage is then pulse-width modulated to replicate a sinusoidal current at the desired frequency and voltage.

Nomenclature
The model number of the drive includes the power rating and nominal voltage input to the drive. Figure 3 provides a complete explanation of all of the alpha and numeric characters in the drive model number.

Temperature & Humidity
Drive operating temperature range: -20°C to 60°C

Drive storage temperature range: -40°C to 85°C

Maximum Relative Humidity: 95%

Electric shock hazard. Disconnect and lock out power before servicing. Discharge all capacitors before servicing.

Check the drive carefully before using it. Make sure that all wires are correctly and tightly connected. Improper operation may cause fire or injury to persons.

WARNING

Power On/Off

The drive should use rated AC power supply: 50/60Hz, 380-480V on EV20XXM-KX-XXX models and 208-240V on EV20XXM-JX-XXX drive models. Wrong use of power supply voltage levels may cause drive to be damaged. User should check the power supply, drive model being used before powering on the drive. When power off the drive, make sure to wait at least 10 minutes to ensure that the drive is completely turned off.

NOTICE

Communication Setting
The drive is designed to be used in a master-slave configuration where the master is a unit controller.
Input Voltage and Input Current
The drives are designed for rated AC power supply: 50/60Hz, 380-480V on EV20XXM KX-XXX models and 208-240V on EV20XXM-JX-XXX drive models.

Power Factor Correction
Drive has passive power factor correction, which is capable of improving efficiencies.

Speed Control
The frequency range of the drive is from 15Hz to 120Hz. If the frequency set by unit controller is less than 15Hz but not zero, then the compressor will work at 15Hz. Similarly, if the frequency set by unit controller is greater than 120Hz, then the compressor will work at 120Hz.

There are three cases for unit shut down.

Case I (Controlled shut down): Unit shut down the compressor.

Case II (Faulted condition): When drive faults occur, the drive will shut down the compressor. Major and minor faults have different shutdown sequences. For major faults, the drive trips the compressor immediately (from running frequency to zero frequency). For minor faults, it has the same sequence as Case I. As mentioned above clear faults using the 'Fault Clearing' method shown below.

Case III: Loss of power shut down, this control procedure is the same as major fault shut down.

Fault Clearing
Faults are cleared through unit controls interface.

Status Indication
There are two control chips on the drive board and all of them have their own LED for status display. COMMS MCU has three LED indicators, DSP has one LED indicator.

LED for COMMS MCU

Operation Indicating LED (Green LED805)
When the drive is in normal state (no protection and fault), the drive is in standby state and the compressor does not work, the LED will blink every 2 seconds. If the compressor is running, the LED will always be on.

Protection Indicating LED (Yellow LED804)
When the drive is under protection, the yellow LED will blink. Refer to Troubleshooting Table for more information.

Hardware Fault Indicating LED (Red LED803)
When the drive is under hardware fault, the red LED will blink. Refer to Troubleshooting Table for more information.

LED for Drive Control DSP Chip (Green LED802)
When the drive is in normal state, whether the compressor is running or standby, the LED will blink every 1 second. When the drive is under protection or hardware fault, the LED will blink every 1/8 of a second.
Drive Over Temperature Protection
The drive is self protected against high internal temperatures. There are different modes of protection; temperature high and foldback. For foldback protection refer to Table 8 for more information.

Power Interrupt
Power interrupts can result in a drive trip that won't harm the drive. The drive can withstand interrupts of a short duration (1-2 power cycles), but will trip on anything longer.

Air Cooled Heat Exchanger
Drives cooled by the aluminum air cooled heat exchanger are designed to be in the air flow stream of the condenser.

Foldback
To protect the drive components or the compressor, the compressor speed will ‘foldback’ or slow down to help reduce risk to components. The foldback event(s) will be flagged in the unit controller. This will allow the operating system to respond and mitigate the conditions causing foldback.

Troubleshooting
The drive may indicate fault or protection for various reasons. If fault or protection occurs, users should power down the drive, check the drive, and check the drive running condition carefully. For the description, check and handling of these faults or protections, please refer to Troubleshooting Table.

The yellow and red LED of COMM will be displayed in a circulation of blinking for N times (N is the protection code) then be off for 3 seconds. For detailed description of the protections, please refer to Troubleshooting Table.

- Immediate shutdown = The drive will execute an immediate shut down due to a condition that may cause damage to the drive.
- Controlled shutdown = The drive will execute a controlled shut down due to systemic or temperature related problems.
- First faults latched = When a fault occurs it may cause other faults to happen as well. In order to capture the fault that happened first, these registers only record the ‘first fault latched’.
- Current faults = These registers display all faults that are currently logged by the drive, including the first faults latched.

Variable Speed Compressor Temperature Control

WattMaster VCC-X Unit Controller and WattMaster Refrigerant System Module for Copeland VFD Compressors (RSMVC-P) work together to control the unit operation and control the variable speed compressor capacity.

The RSMVC-P Module provides the following:
• Controls the Compressors to satisfy the Supply Air Temperature Setpoint (Supply Air Temperature sent by VCCX-P Controller) during Cooling Mode. During Dehumidification Mode, it controls the Compressors to the Suction (Saturation) Temperature Setpoint
• Communicates to the Copeland VFD Drive for control and fault monitoring
• Modulates the Condenser Fan to maintain the Head Pressure Setpoint
• Provides alarms and safeties for the compressor and condenser operation.
• Contains a 2 x 8 LCD character display and 4 buttons that allow for status display, setpoint changes, and configuration changes.

Cooling Mode Operation
In the Cooling Mode, as the Supply Air Temperature (SAT) rises above the Active SAT Cooling Setpoint, the compressors will stage on and modulate to maintain the Active SAT Cooling Setpoint. Minimum off times must also be met before compressors can stage on and minimum run times must be met before compressors can stage off.

For more information about the VCC-X Controller or RSMVC-P Controller reference the VCC-X Controller Technical Guide (V57140) and the RSMVC-P Technical Guide (V73400).
Modular Silicon Expansion Valve and Universal SuperHeat Controller/Sensor Hardware Installation

Additional Product Markings for USHC-G1.3b and USHS-G1.3b
- Operating Control
- Independently Mounted
- Pollution Degree 2
- Impulse Voltage: 300 V
- SELV Circuit Voltage I/O
- Operating Pressure: 21 to 240 psia
- Proof Pressure: 600 psi
- Burst Pressure: 1500 psi

About the MSEV and USHX
The Modular Silicon Expansion Valve (MSEV) shown in Figure 7, is a two-stage proportional control expansion valve which utilizes DunAn Microstaq’s patented silQflo™ microelectromechanical systems microvalve technology to provide precise mass flow control for industry-standard HVAC and refrigeration applications. The MSEV consists of a MEMS pilot valve which acts as a first stage valve that applies varying fractions of fluid line pressure onto the second stage spool valve according to the command signal provided by the Universal SuperHeat Controller (USHC). The MSEV is installed at the inlet of the evaporator.

The Universal SuperHeat Controller/Sensor (USHX), shown in Figure 8 is offered either as a:

a. Universal SuperHeat Controller (USHC): To drive and control the MSEV.

b. Universal SuperHeat Sensor (USHS): To measure and report temperature, pressure, and superheat values.

The USHX consists of an internal MEMS pressure sensor and a processing unit. It uses a wiring harness, shown in Figure 9, to measure the evaporator temperature and control the MSEV. The USHX is installed at the outlet of the evaporator; it mounts onto a ¼” access fitting and utilizes the Modbus RTU communication protocol for user interaction. The USHX and its wiring harness pin assignments are shown in Table 9.

Mechanical Installation
This section describes the mechanical installation of the MSEV and USHX. Figure 10 below shows an example of a typical system the MSEV and USHX devices would be integrated into. Like conventional thermostatic expansion valves (TXVs) or electronic expansion valves (EEVs), the MSEV is installed at the inlet of the evaporator. The USHC, which drives and controls the MSEV, is installed at the outlet of the evaporator, in place of the TXV bulb or EEV controller sensing device. The MSEV and USHC are connected together by a wiring harness. A thermistor at the outlet of the evaporator measures the temperature, and the USHC is powered by the Class 2 power source.

WARNING
Do not turn the power source ON until installation of MSEV, USHX and wiring harness is complete. For the user’s own safety, only Class 2 power source should be used to power the MSEV and USHX devices.
Installing the MSEV
To install the MSEV, complete the following steps:

1. Pump down and recover any residual refrigerant from the system.
2. Remove the current TXV and its bulb or EEV and its controller by cutting. Take care to minimize the risk of introducing contaminants into the system when removing the existing valve.
3. Before continuing, clean the copper connections of the MSEV. The MSEV comes with a standard 3/8” outside diameter (OD) copper tubes that are 3” in length on both sides of the main body.
   a. Do not reduce the length of the copper tubes when brazing.
   b. Flare fittings should be used if the copper tubes length is reduced.
4. Position the MSEV as displayed in Figure 11 and ensure the arrow mark aligns with the direction of fluid flow. The blue arrows show which way fluid is supposed to flow through the valve. Also ensure that the MSEV is installed in an upwards orientation or at any angle less than 90° in either direction (represented by the curved green arrows).
   a. The MSEV cannot be installed in a downwards orientation (shown in curved red arrows). It will not function as intended if installed in such a way.
5. Wrap the valve body with a wet cloth before brazing.
6. Connect the MSEV to the inlet of the evaporator by brazing. Allow the valve to air-cool after brazing.
7. It is mandatory to install a brand new filter drier at the inlet of the MSEV as indicated in Figure 10. It can be installed at about 6” away from the MSEV. The MSEV must be protected against contaminants to ensure its optimal operation.

a. While brazing, direct heat away from the valve body. Ensure that the temperature of the valve body does not exceed 221°F (105°C).

8. The MSEV installation process is now complete.

Figure 11 - MSEV installation orientation
**Installing the USHX**

To install the USHX, complete the following steps:

1. Pump down and recover any residual refrigerant from the system. This may have already been done if a MSEV was installed before this step.
2. Obtain any ¼” access fitting that is compatible with the system. In this section, a ¼” access fitting with a 3/16” OD extended tube is used as an example to demonstrate the installation process.
3. See Figure 12 and Figure 13 for the proper orientation of the USHX. When installing the device on a horizontal copper line as shown in Figure 12, the USHX can only be installed up to a 45° angle from the vertical axis in either direction (represented by the curved green arrows). When installing the device on a vertical copper line as shown in Figure 13, the USHX cannot be installed at a downward angle (represented by the red arrow).
4. Drill a hole into the copper line that extended tubes may fit in to. The location of this hole should be about 6” away from the outlet of the evaporator.
   a. Care must be taken to not introduce copper shavings into the copper line while the hole is being drilled.
5. Remove the valve core of the access fitting before brazing.
6. Braze the access fitting to the copper line and allow it to air-cool after brazing.
7. Place the valve core back onto the access fitting and tighten the connection. This step completes the installation of the ¼” access fitting. The final result should look similar to what is shown below in Figure 14.
8. Mount the USHX onto the access fitting. Turn the USHX housing clockwise by hand until some resistance is met and then use 7/16” and 9/16” wrenches in tandem as shown below in Figure 15 to further tighten the USHX connection. This will ensure that the brazed joint is not damaged by the torque of the tightening.

9. Attach the wiring harness (10-pin connector) to the USHX as shown below in Figure 15.
   a. If the USHX is located in a wet or potentially wet environment, apply silicone grease inside the 10-pin connector of the wiring harness.

10. Install the thermistor at the outlet of the evaporator and close to the access fitting using a zip tie, as shown below in Figure 16. The thermistor should be located at either the 10 o’clock or 2 o’clock position only.
   a. Ensure that the thermistor wire is not tied down to the tubing. The zip tie should only be tied around the thermistor body.
   b. Apply thermal grease between the thermistor and the copper line to obtain the most accurate temperature readings.

WARNING
Do not turn the power source ON during the installation of the wiring harness.
11. Wrap the thermistor with the insulation material and secure the insulation in place using a zip tie. The final result should be similar to what is shown below in Figure 17.

![Figure 17 - Insulation secured to the thermistor](image)

12. Check for leaks at all the braze joints after brazing.
13. Pull a vacuum on the system until 250 microns is reached.
14. Restore refrigerant to the system.
15. Perform another check for leaks at all braze joints.
16. Refer to Electrical Wiring section to complete the electrical wiring of the system.
17. Refer to USHX Software User Interface Manual to set up communications between the USHX and the computer.
18. Supply power to the USHX with a power supply and power it on.
19. Ensure that the settings in the GUI meet the system requirements (i.e. double check the Refrigerant, Target Superheat, Device Mode, and other settings).
20. Power on the HVAC/R system and the MSEV and USHX will automatically begin functioning.
21. Observe the superheat temperature values in the GUI Status tab to ensure that the system is performing nominally. Adjust the system settings through the GUI if necessary.

**Electrical Wiring**

After the mechanical installation of the MSEV(s) and/or USHX(s) into the system, complete the electrical wiring of the system by completing the following steps.

**Single USHC-MSEV or Single USHS**

![WARNING]

**WARNING**

Do not turn the power source ON until all electrical wiring setup is complete.

1. Check the voltage type – either 12 V or 24 V – of the MSEV. It can be found on the MSEV model number label. The power source required will be based on the MSEV voltage type.

![WARNING]

**WARNING**

Ensure that the power source voltage matches the MSEV voltage type. If a 12 V MSEV is powered by a 24 V power source, the MSEV will fail due to an over-voltage. If a 24 V MSEV is powered by a 12 V power source, the MSEV will not fully open due to an under-voltage.
2. Obtain a Class 2 24 VAC transformer with a capacity of 40 to 100 VA and an output of 24 VAC at a frequency of 60 Hz. Alternatively, a 120 VAC to 12 VDC or 120 VAC to 24 VDC Class 2 step-down power supply with a 40 to 100 W power rating may be used. The schematics of the power sources are shown below in Figure 18.

a. For the user’s own safety, only Class 2 power sources should be used to power the MSEV and USHX devices.

3. Double check the power source output voltage (AC transformer secondary or DC power supply output).
   a. The reading should be at or near 12 VDC, 24 VDC, or 24 VAC depending on the MSEV and power source. When supplying 24 V, the voltage must be within the range of 20.4 V to 27.6 V. When supplying 12 V, the voltage must be within the range of 10.2 V to 13.8 V.

![Figure 18 - Class 2 DC and AC power sources](image-url)
4. Once the power source output voltage has been identified and checked to be accurate, ensure that the power supply is off before continuing with the steps below.

5. The power input wires (18 AWG red/black wires) on the wiring harness should be connected to the power source as shown below in Figure 19.
   a. The USHX power input wires are non-polar, so the wire ordering and colors are not significant for the purposes of this step in the procedure. All connectors used between the USHX, power source, and MSEV should be UL-approved.
   b. The wiring schemes of the ‘Single USHC-MSEV Setup’ and ‘Single USHS Setup’ are the same except that the PWM output wires of the USHS for the ‘Single USHS Setup’ process should be disconnected, terminated with wire nuts, and wrapped with electrical tape so that they do not form short circuits with each other or any other wires or metal surfaces. As for the ‘Single USHC-MSEV Setup’ process, the PWM output wires should be connected to the MSEV as shown below in Figure 19.

![Figure 19 - Single USHC-MSEV or single USHS wiring diagram](image-url)
6. Connect the RS485 communication wires (2-wire gray cord that contains a red and a black wire and the green data ground wire) to the D+, D-, and SG terminals on the USB-to-RS485 converter as shown below in Figure 20. For the USHX setup, the RS485 will require an adapter with built-in electrical isolation.

![Figure 20 - USHX-to-RS485 converter connection](image)

7. Connect the RS485 adapter box to the computer via a USB port.
8. Connect the PWM output wires (two 18 AWG white wires) to the MSEV electrical connections, shown below in Figure 21. These wires are non-polar.

![Figure 21 - MSEV electrical connections](image)

9. The general purpose wires (20 AWG brown/purple wires), if they exist on the harness, must remain unconnected, be terminated with wire nuts, and wrapped with electrical tape so that they do not form short circuits with each other or any other wires or metal surfaces.

10. Tape any dangling wires to existing structures such as copper and water lines with at least 4-5 sections of electrical tape each. Use zip ties on top of the electrical tape in a neat and organized manner to further secure the wires.

![WARNING](image)

**WARNING**
Ensure that all cables are distanced from fans, high voltage wires (120-208 VAC), and potential areas of water. Ensure that any bare cable leads are covered with electrical tape and do not touch other wire leads or any metal structures.

11. The electrical wiring for a single USHC-MSEV setup or a single USHS setup is now complete.
**Troubleshooting**
The following section describes troubleshooting procedures for the USHX and MSEV. If the system is running abnormally, first check the wiring for broken or shorted connections. Repair broken wires and remove short circuits between touching wires or between wires and any metal surfaces. If there are no wiring problems, then use the following table to further diagnose the problem (assuming everything else in the system such as the compressor, evaporator, filter drier, etc. is working properly).

<table>
<thead>
<tr>
<th>Problem</th>
<th>Possible Cause</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>High Superheat:</td>
<td><strong>Inadequate Power to the Valve</strong></td>
<td>Check the power source voltage. The voltage leaving the transformer and entering the USHX should be close to the intended supply voltage (24V or 12V). If the transformer voltage is too low, there is a problem with the transformer or its wiring. If the voltage entering the USHX is low and the transformer voltage is normal, there is a problem with the terminal connections or interconnecting wiring to the USHX.</td>
</tr>
<tr>
<td></td>
<td><strong>Temperature Sensor Incorrectly Mounted</strong></td>
<td>Check the mounting of the USHC temperature sensor. The sensor should be firmly mounted to the outlet of the evaporator at a 10 o’clock or 2 o’clock position. Check that the temperature sensor is wrapped with insulated tape.</td>
</tr>
<tr>
<td></td>
<td><strong>Over Voltage to MSEV</strong></td>
<td>Check the resistance across the valve terminals. Remove both power connections from the MSEV and measure its resistance with a multimeter. The resistance reading should be between 26-34 Ω for a 24 V valve and between 6-13 Ω for a 12 V valve. If the resistance is significantly out of this range (or zero), the MSEV is damaged and should be replaced.</td>
</tr>
<tr>
<td></td>
<td><strong>MSEV Slow to Open</strong></td>
<td>Check that the USHX Gain settings meet the system requirements. (Also applicable if the MSEV opens too quickly.) Connect and disconnect the power to the valve several times to manually actuate the valve.</td>
</tr>
<tr>
<td>Low Superheat:</td>
<td><strong>MSEV Slow to Close</strong></td>
<td>Check that the USHX Gain settings meet the system requirements. (Also applicable if the MSEV closes too quickly.) Connect and disconnect the power to the valve several times to manually actuate the valve.</td>
</tr>
<tr>
<td></td>
<td><strong>Temperature Sensor Incorrectly Mounted</strong></td>
<td>Check the mounting of the USHC temperature sensor. The sensor should be firmly mounted to the outlet of the evaporator at a 10 o’clock or 2 o’clock position. Check that the temperature sensor is wrapped with insulated tape.</td>
</tr>
<tr>
<td></td>
<td><strong>Severely Oversized Valve</strong></td>
<td>Determine the capacity of the evaporator and check the valve model number to confirm that the two are compatible regarding their capacities.</td>
</tr>
</tbody>
</table>

*This may indicate that the MSEV is not fully opening. Common symptoms include compressor short cycling.*

*This may indicate that the MSEV is staying open. Common symptoms include compressor frosting.*
